Stephens Category:Films shot in New Orleans Determination of ciprofloxacin in human plasma by reversed-phase high-performance liquid chromatography. A simple high-performance liquid chromatographic method has been developed and validated for the determination of ciprofloxacin (CIP) in human plasma. The method involves protein precipitation and liquid-liquid extraction followed by reversed-phase high-performance liquid chromatography using an isocratic mobile phase of acetonitrile-phosphate buffer, pH 5.0 (80:20, v/v) on a Betasil C(18) column. The detector response for CIP was linear over the

range of 0.6-30 microg/mL. The method was validated over the concentration range of 0.6-30.0 microg/mL for CIP in human plasma. The detection limit of the assay was 0.2 microg/mL. The accuracy and precision of the method over the entire concentration range tested were between 91.4 and 108.4% and 1.3 and 9.7%, respectively. The method was successfully applied to measure the concentrations of CIP in human plasma samples. Palmitoylation and deglutathionylation of major membrane glycoprotein of hamster spermatozoa. The acrosome of hamster spermatozoa has two major glycoproteins named Acrosin I and Acrosin II [1]. Both glycoproteins are localized in the acrosomal matrix. After acrosome reaction, these glycoproteins are translocated to the surface of the spermatozoon where they are thought to be involved in acrosome reaction by the proteolytic action of Acrosin I [1]. Spermatozoa are rich in unsaturated fatty acids and show a high potential for lipid peroxidation.
